How inflation affects your salary?

While nominal wages in Poland have shown a strong upward trend between 2014 and 2024, skyrocketing inflation (HICP) drastically eroded this growth.

A clear reflection of this is our "Bread Test": despite a much higher nominal salary on paper, the real purchasing power of an average wage actually shrank by over 120 loaves of bread within a decade.

As a result, the growth of real purchasing power was significantly halted, highlighting that higher earnings did not fully translate into greater financial security for citizens.

Inflation (HICP) vs. Currency Exchange Rates

What does this mean for your savings?

If you saved **10 000 PLN** in **2014**, you could exchange it for about **2 392 EUR** or **3 175 USD**. Ten years later, in **2024**, that exact same amount of zlotys gives you the same **2 320 EUR** (since the EUR to PLN rate stayed stable), but only **2 513 USD**.

Key takeaway: High local inflation (which peaked in 2022) combined with global crises caused the Polish Zloty to lose massive ground against the US Dollar. Your purchasing power in USD dropped by **nearly 33%**.
